

Week 2 – Design Studio

"A résumé screening system rejected a qualified candidate. Write the requirements it should have had, and design the measurement that would have told you."

The category is real. Amazon built a résumé screener in the mid-2010s and scrapped it after discovering it had learned to penalize résumés containing the word "women's."

Format. Build in pairs — one page, argue, merge. Then we review as a group. The answers document is handed out after.

Two halves, one page.

1. **The requirements.** Three to five of them, each as a rate, on a slice, with a remainder policy and an owner. At least one slice should be a group the model cannot see directly.
2. **The measurement.** For each requirement: where do the résumés with a known right answer come from, and who decides what "qualified" means? How many do you need on that slice before the number means anything? What would you run, and what would the report look like?

A rule for this one. You may not answer with "make the model more accurate." More accurate than what, on whom, measured how?
